8	0	2	0	2000
0	0	0	0	5100

The mapping offset function I use is f(n) = 13\*Location+4\*Time+ 1\*Item which ensure each combination of two sets do not equal to the third set. And that ensure the uniqueness of the offset value.

## Q2:

(1)For Naïve Bayes classifier, xi belong to class yi if P(xi|yi) is the maximum probability among all the i numbers. So according to the assumption, there are two classes 0 and 1, and x is a binary vector. In order to make Naïve Bayes to be a binary classifier:

NB(X)=1 if P(y=1|x)/ P(y=0|x)>1,

NB(X)=0 if P(y=1|x)/ P(y=0|x)<1

So we should find how to represent P(y=1|x)/P(y=0|x), then

$$NB(x) = \begin{cases} 1 & \text{if } \frac{P(y=1|x)}{P(y=0|x)} > 1 \\ 0 & \text{if } \frac{P(y=1|x)}{P(y=0|x)} < 1 \end{cases}$$

According to Bayes Rules,

$$\frac{P(y=1|x)}{P(y=0|x)} = \frac{P(x|y=1) \cdot P(y=1)}{P(x)} \cdot \frac{P(x)}{P(x|y=0) \cdot P(y=0)}$$

$$= \frac{P(x|y=1) \cdot P(y=1)}{P(x|y=0)} \cdot \frac{P(x|y=0)}{P(x|y=0)}$$

$$= \frac{P(y=1)}{P(y=0)} \cdot \frac{n}{i=1} \cdot \frac{P(xi|y=0)}{P(xi|y=0)}$$

where n represents the different feature vectors in X

Set 
$$a_i = P(x_i = 1 | y = 1)$$
, then  
 $1 - a_i = P(x_i = 0 | y = 1)$ , so  
 $P(x_i | y = 1) = a_i$ ,  $(1 - a_i)$ 

Similarly, set 
$$\mathcal{B}_{i} = P(x_{i=1}|y=0)$$
, so  $1-\mathcal{B}_{i} = P(x_{i=0}|y=0)$ , then  $P(x_{i}|y=0) = \mathcal{B}_{i}^{x_{i}} \cdot (1-\mathcal{B}_{i})^{x_{i}}$ 

So  $P(y=1) = P(x_{i}|y=1)$ 
 $P(y=0) = P(y=1) = P(x_{i}|y=0)$ 

$$= \frac{P(y=1)}{P(y=0)} \cdot \prod_{i=1}^{n} \frac{\mathcal{A}_{i}^{x_{i}} \cdot (1-\mathcal{B}_{i})^{x_{i}}}{\mathcal{B}_{i}^{x_{i}} \cdot (1-\mathcal{B}_{i})^{x_{i}}}$$

Apply  $\log$  function on above equation, then  $\log \frac{P(y=1)}{P(y=0)} + \sum_{i=1}^{n} \log \frac{\mathcal{A}_{i}^{x_{i}} \cdot (1-\mathcal{B}_{i})^{x_{i}}}{\mathcal{B}_{i}^{x_{i}} \cdot (1-\mathcal{B}_{i})^{x_{i}}}$ 

For the RHS part
$$\sum_{i=1}^{n} \log \frac{\mathcal{A}_{i}^{x_{i}} \cdot (1-\mathcal{A}_{i})^{x_{i}}}{\mathcal{B}_{i}^{x_{i}} \cdot (1-\mathcal{B}_{i}^{x_{i}})^{x_{i}}}$$

$$= \sum_{i=1}^{N} \left[ \log \frac{\lambda^{i}}{\lambda^{i}} + \log \left( 1 - \lambda^{i} \right)^{1 - \lambda^{i}} - \log \frac{\lambda^{i}}{\lambda^{i}} - \log \left( 1 - \lambda^{i} \right)^{1 - \lambda^{i}} \right]$$

$$= \sum_{i=1}^{N} \left[ \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} - \lambda^{i} \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right]$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} - \lambda^{i} \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{1 - \lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{\lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{\lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{\lambda^{i}}{1 - \beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{\lambda^{i}}{\beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{\lambda^{i}}{\beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i}} + \log \frac{\lambda^{i}}{\beta^{i}} \right)$$

$$= \sum_{i=1}^{N} \left( \lambda^{i} \log \frac{\lambda^{i}}{\beta^{i$$

Now I define P(y=1|x)/P(y=0|x) to the  $y=wx_i+b$ , so the Naïve Bayes Classifier can be applied on Linear Classification.

The values of w and b are on the above pictures.

(2) For Naïve Bayes Classifier, the value of w can be learned by different probabilities, and these probabilities are depend on the assumption and dataset (various from the number of feature vectors and different classes). So the cost of compute the NB Classifier is cheap.

For Logistic Regression Classifier, the parameter w should be learned by gradient ascent, which may meet the local maximum problem and sometimes hard to learn. So it is unstable.

But for NB Classifier, it uses the assumption that attributes are conditionally independent. So the calculation is easier if we do the smoothing.

What's more, NB Classifier also give another prior probability which may help the confidence of the final result.

Q3:

(1) For the liklihood function

$$L(P_{i,j} | \theta) = P(P_{i,j} | \theta)$$

$$= P(P_{i,j} | \theta) \cdot P(P_{i,2} | \theta) \cdot P(P_{i,3} | \theta) \cdots P(P_{2,3} | \theta)$$

$$= P(P_{i,i} | \theta) \cdot P(P_{i,2} | \theta) \cdot P(P_{i,3} | \theta) \cdots P(P_{2,3} | \theta)$$

According to the assumption,

$$P(i,j) = P(0_{j} | S_{i})$$

$$P(S_{i}) = Q_{i}$$

$$Q_{j} = \sum_{i=1}^{2} P_{i,j} P_{i}$$

The log liklihood function is

$$P(P_{i,j} | \theta) = Q_{i} \cdot Q_{i} \cdot Q_{i}$$

$$= \sum_{j=1}^{2} (u_{j} \log Q_{j})$$

$$= \sum_{j=1}^{2} (u_{j} \log Q_{j})$$

$$= \sum_{j=1}^{2} (u_{j} \log Q_{j})$$

(2) 
$$q_2 = 1 - \hat{q}_1$$
  
According to (1)  
the log likelihood function is  

$$[(\theta) = 0.3 \log[0.12, + 0.4(1-2, 1)] + 0.2 \log[0.29, + 0.8(1-2, 1)]$$

$$+ 0.5 \log[0.79, + 0.1(1-2, 1)]$$

$$\frac{2l}{2q} = \frac{-0.0\hat{q}}{0.4 - 0.3q_1} + \frac{-0.0\hat{q}}{0.5 - 0.3q_1} + \frac{0.3}{0.6q_1 + 0.1}$$
Let  $\frac{2l}{2q} = 0$   $\implies 570q_1^2 - 1179q_1 + 531 = 0$   
 $q_{11} = 0.635$   $q_{12} = 1.548$  (invalid)  
So  $q_{2} = 1 - q_{1} = 0.365$ 

Therefore, the expected percentage of each component is:

$$0_1 = 0.19_1 + 0.49_2 = 0.2095$$

$$0_2 = 0.29_1 + 0.59_2 = 0.3095$$

$$0_3 = 0.79_1 + 0.19_2 = 0.481$$
